# GLOBAL COMPLEXITY BOUND OF A PROXIMAL ADMM FOR LINEARLY-CONSTRAINED NONSEPARABLE NONCONVEX COMPOSITE PROGRAMMING\*

4

### WEIWEI KONG<sup>†</sup> AND RENATO D.C. MONTEIRO<sup>‡</sup>

5 Abstract. This paper proposes and analyzes a dampened proximal alternating direction method 6 of multipliers (DP.ADMM) for solving linearly-constrained nonconvex optimization problems where 7 the smooth part of the objective function is nonseparable. Each iteration of DP.ADMM consists of: (ii) a sequence of partial proximal augmented Lagrangian (AL) updates, (ii) an under-relaxed 8 9 Lagrange multiplier update, and (iii) a novel test to check whether the penalty parameter of the AL function should be updated. Under a basic Slater point condition and some requirements on 10 the dampening factor and under-relaxation parameter, it is shown that DP.ADMM obtains an ap-11 proximate first-order stationary point of the constrained problem in  $\mathcal{O}(\varepsilon^{-3})$  iterations for a given 12 13numerical tolerance  $\varepsilon > 0$ . One of the main novelties of the paper is that convergence of the method is obtained without requiring any rank assumptions on the constraint matrices. 14

15 **Key words.** proximal ADMM, nonseparable, nonconvex composite optimization, iteration 16 complexity, under-relaxed update, augmented Lagrangian function

17 **AMS subject classifications.** 65K10, 90C25, 90C26, 90C30, 90C60

18 **1. Introduction.** Consider the following composite optimization problem:

19 (1.1) 
$$\min_{x \in \mathbb{R}^n} \left\{ \phi(x) := f(x) + h(x) : Ax = d \right\},$$

where h is a closed convex function, f is a (possibly) nonconvex differentiable function on the domain of h, the gradient of f is Lipschitz continuous, A is a linear operator,  $d \in \mathbb{R}^{\ell}$  is a vector in the image of A (denoted as Im(A)), and the following B-block structure is assumed:

$$n = n_1 + \ldots + n_B, \quad x = (x_1, \ldots, x_B) \in \mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_B}$$

24 (1.2)  
25 
$$h(x) = \sum_{t=1}^{B} h_t(x_t), \quad Ax = \sum_{t=1}^{B} A_t x_t,$$

where  $\{A_t\}_{t=1}^B$  is another set of linear operators and  $\{h_t\}_{t=1}^B$  is another set of proper closed convex functions with compact domains.

Due to the block structure in (1.2), a popular algorithm for obtaining stationary points of (1.1) is the proximal alternating direction method of multipliers (ADMM) wherein a sequence of smaller augmented Lagrangian type subproblems is solved over  $x_1, ..., x_B$  sequentially or in parallel. However, the main drawbacks of existing ADMMtype methods include: (i) strong assumptions about the structure of h; (ii) iteration

complexity bounds that scale poorly with the numerical tolerance; (iii) small stepsize parameters; or (iv) a strong rank assumption about the last block  $A_B$  that implies  $\operatorname{Im}(A_B) \supseteq \{d\} \cup \operatorname{Im}(A_1) \cup \ldots \operatorname{Im}(A_{B-1})$  which we refer to as the *last block condition*. Of the above drawbacks, (iv) is especially limiting. To illustrate this, we give a few applications where the last block condition, and hence (iv), does not hold:

> Rank-deficient Quadratic Programming (RDQP). It is shown in [4] that the(non-proximal) ADMM diverges on the following three-block convex RDQP:

40  $\min_{x_1, x_2, x_3, x_4} \frac{1}{2} x_1^2$ 

4

1 s.t. 
$$\begin{pmatrix} 1 & 1 \\ 1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} x_3 + \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix} x_4 = 0.$$

43  $\triangleright$  Distributed Finite-Sum Optimization (DFSO). Given a positive integer B, 44 consider:

45 (1.3) 
$$\min_{x_i \in \mathbb{R}^n} \left\{ \sum_{t=1}^B (f_t + h_t)(x_t) : x_t - x_B = 0, \quad t = 1, \dots, B - 1 \right\}$$

46 where  $f_i$  is continuously differentiable,  $h_t$  is closed convex, and  $\nabla f_t$  is Lip-47 schitz continuous for t = 1, ..., B. It is easy to see<sup>1</sup> that (1.3) is a special 48 case of (1.1) where we have  $A_s = e_s \otimes I \in \mathbb{R}^{n(B-1) \times n}$  for s = 1, ..., B-1, 49 we have  $A_B = -1 \otimes I \in \mathbb{R}^{n(B-1) \times n}$ , and d = 0. Moreover, it is straightfor-50 ward to show that for s = 1, ..., B-1 we have  $\operatorname{Im}(A_s) \cap \operatorname{Im}(A_B) = 0$  but 51  $\operatorname{Im}(A_s) \setminus \{0\} \neq \emptyset$ , which implies that  $\operatorname{Im}(A_s) \not\subseteq \operatorname{Im}(A_B)$ .

52  $\triangleright$  Decentralized AC Optimal Power Control (DAC-OPF). The convex version 53 was first considered in [27] for the rectangular coordinate formulation, and 54 the problem itself is considered one of the most important ones in power 55 systems decision-making. The nonconvex version of DAC-OPF is a variant 56 where  $h_t$  is the indicator of a convex region given by a finite number of com-57 plicated quadratic constraints and  $f_t$  is a nonconvex quadratic cost function. 58 A discussion of the limitations induced by assuming any rank condition which 59 implies the last block condition is given in [29].

Our goal in this paper is to develop and analyze the complexity of a proximal ADMM that removes all the drawbacks above. For a given  $\theta \in (0, 1)$ , its  $k^{\text{th}}$  iteration is based on the *dampened* augmented Lagrangian (AL) function given by

63 (1.4) 
$$\mathcal{L}^{\theta}_{c_k}(x;p) := \phi(x) + (1-\theta) \langle p, Ax - d \rangle + \frac{c_k}{2} \|Ax - d\|^2,$$

where  $c_k > 0$  is the *penalty parameter*. Specifically, it consists of the following updates: given  $x^{k-1} = (x_1^{k-1}, \ldots, x_B^{k-1}), p^{k-1} c_k, \chi$ , and  $\lambda$ , sequentially  $(t = 1, \ldots, B)$  compute the t<sup>th</sup> block of  $x^k$  as

$$\begin{array}{l} {}_{68} \quad (1.5) \qquad x_t^k = \mathop{\mathrm{argmin}}_{u_t \in \mathbb{R}^{n_t}} \left\{ \lambda \mathcal{L}^{\theta}_{c_k}(\ldots, x_{t-1}^k, u_t, x_{t+1}^{k-1}, \ldots; p^{k-1}) + \frac{1}{2} \| u_t - x_t^{k-1} \|^2 \right\},$$

70 and then update

(1.6) 
$$p^{k} = (1-\theta)p^{k-1} + \chi c_{k} \left(Ax^{k} - d\right),$$

<sup>1</sup>Here,  $e_1, \ldots, e_n$  is the standard basis for  $\mathbb{R}^{B-1}$ ,  $I_n$  is the *n*-by-*n* identity matrix,  $\mathbf{1} \in \mathbb{R}^{B-1}$  is a vector of ones, and  $\otimes$  is the Kronecker product of two matrices.

- where  $\chi \in (0, 1)$  is a suitably chosen under-relaxation parameter.
- 73 Contributions. For proper choices of the stepsize  $\lambda$  and a non-decreasing sequence of
- penalty parameters  $\{c_k\}_{k>1}$ , it is shown that if the Slater-like condition<sup>2</sup>

75 (1.7) 
$$\exists z_{\dagger} \in \operatorname{int} (\operatorname{dom} h) \text{ such that } Az_{\dagger} = d$$

<sup>76</sup> holds, then DP.ADMM has the following features:

<sup>77</sup> ▷ for any tolerance pair  $(\rho, \eta) \in \mathbb{R}^2_{++}$ , it obtains a pair  $(\bar{z}, \bar{q})$  satisfying

78 (1.8)  $\operatorname{dist}\left(0,\nabla f(\bar{z}) + A^*\bar{q} + \partial h(\bar{z})\right) \le \rho, \quad \|A\bar{z} - d\| \le \eta$ 

79 in  $\mathcal{O}(\max\{\rho^{-3}, \eta^{-3}\})$  iterations;

80  $\triangleright$  it introduces a novel approach for updating the penalty parameter  $c_k$ , instead 81 of assuming that  $c_k = c_1$  for every  $k \ge 1$  and that  $c_1$  is sufficiently large (such 82 as in [3, 14, 15, 28, 31, 32]);

*Related Works.* Since ADMM-type methods where f is convex have been well-studied in the literature (see, for example, [1, 2, 5, 6, 7, 8, 9, 10, 11, 12, 23, 24, 25]), we make no further mention of them here. Instead, we discuss below ADMM-type methods where

88 f is nonconvex.

Letting  $\delta_S$  denote the indicator function of a convex set S (see Subsection 1.1), we first present a list of common assumptions in Table 1.1.

> $\mathcal{Q} \quad f(z) = \sum_{t=1}^{B} f_t(z_t) \text{ for subfunctions } f_t : \operatorname{dom} h_t \mapsto \mathbb{R}.$   $\mathcal{R}_0 \quad \operatorname{Im}(A_B) \supseteq \{d\} \cup \operatorname{Im}(A_1) \cup \ldots \cup \operatorname{Im}(A_{B-1}).$   $\mathcal{S} \quad \text{The Slater-like assumption (1.7) holds.}$   $\mathcal{P} \quad h_i \equiv \delta_P \text{ for } i \in \{1, \ldots, B\}, \text{ where } P \text{ is a polyhedral set.}$   $\mathcal{F} \quad A \text{ point } x^0 \in \operatorname{dom} h \text{ satisfying } Ax^0 = d \text{ is available as an input.}$  $\operatorname{TABLE 1.1}$

Common nonconvex ADMM assumptions and regularity conditions.

Earlier developments on ADMM for solving nonconvex instances of (1.1) all as-

sume that  $\mathcal{R}_0$  hold, and the ones dealing with complexity establish an  $\mathcal{O}(\varepsilon^{-2})$  iteration

93 complexity, where  $\varepsilon := \min\{\rho, \eta\}$ . More specifically, [3, 13, 30, 31] present proximal

ADMMs under the assumption B = 2,  $h_B \equiv 0$ , and assumption Q holds for [3,13,30]. Papers [14,15,20,21] present (possibly linearized) ADMMs under the assumption that

96  $B \ge 2, h_B \equiv 0$ , and assumption  $\mathcal{Q}$  holds for [14, 20, 21].

We next discuss papers that do not assume the restrictive condition  $\mathcal{R}_0$  in Table 1.1, and are based on ADMM approaches directly applicable to (1.1) or some reformulation of it. An early paper in this direction is [15], which establishes an  $\mathcal{O}(\varepsilon^{-6})$  iteration-complexity bound for an ADMM-type method applied to a penalty reformulation of (1.1) that artificially satisfies  $\mathcal{R}_0$ . On the other hand, development of ADMM-type methods directly applicable to (1.1) is considerably more challenging and only a few works have recently surfaced (see Table 1.2 below).

We now discuss some advantages of DP.ADMM compared to the other two papers in Table 1.2. First, the method in [28] considers a small stepsize (proportional

<sup>&</sup>lt;sup>2</sup>Here, int S denotes the interior of a set S, dom  $\psi$  denotes the domain of a function  $\psi$ , and  $A^*$  is the adjoint of linear operator A.

Algorithm	θ	χ	Complexity	Assumptions	Adaptive $c$

TABLE 1.2								

Comparison of existing ADMM-type methods with DP.ADMM for finding  $\varepsilon$ -stationary points with  $\varepsilon := \min\{\rho, \eta\}$  and  $\pi_{\theta} = \theta^2 / [2B(2-\theta)(1-\theta)]$  if  $\theta \in (0, 1)$  and  $\pi_{\theta} = 1$  if  $\theta = 1$ .

to  $\eta^2$ ) linearized proximal gradient update while DP.ADMM considers a large step-106 size (proportional to the inverse of the weak-convexity constant of f) proximal point 107 update as in (1.5). Second, the method in [28] requires a feasible initial point, i.e., a 108 point  $z_0 \in \text{dom } h$  satisfying  $Az_0 = d$ , while DP.ADMM only requires that the initial 109 point be in dom h. Third, the methods in [28, 32] both require certain hyperparam-110 eters (the penalty parameter in [28] and an interpolation parameter in [32]) to be 111 chosen in a range that is hard to compute, while DP.ADMM only requires its main 112113 hyperparameter pair  $(\chi, \theta)$  to satisfy a simple inequality (see (2.6)). Moreover, [28] does not specify an easily implementable rule for updating its method's penalty pa-114rameter, while DP.ADMM does. Fourth, convergence of the method in [32] requires 115 h being the indicator of a polyhedral set, whereas DP.ADMM applies to any closed 116 convex function h. Fifth, in contrast to [28] and this work, [32] does not give a com-117 plexity bound for its proposed method. Finally, [28] considers an unusual negative 118 stepsize for its Lagrange multiplier update — which justifies its moniker "scaled dual 119 descent ADMM" — whereas DP.ADMM considers a positive stepsize. 120

Organization. Subsection 1.1 presents some basic definitions and notation. Section 2 presents the proposed DP.ADMM in two subsections. The first one precisely describes the problem of interest, while the second one states the static and dynamic DP.ADMM variants and their iteration complexities. Section 3 and 4 present the main properties of the static and dynamic DP.ADMM, respectively. Section 5 presents some preliminary numerical experiments. Section 6 gives some concluding remarks. Finally, the end of the paper contains several appendices.

1.1. Notation and Basic Definitions. Let  $\mathbb{R}_+$  denote the set of nonnegative real numbers, and let  $\mathbb{R}_{++}$  denote the set of positive real numbers. Let  $\mathbb{R}_n$  denote the *n*-dimensional Hilbert space with inner product and associated norm denoted by  $\langle \cdot, \cdot \rangle$ and  $\|\cdot\|$ , respectively. The direct sum (or Cartesian product) of a set of sets  $\{S_i\}_{i=1}^n$ is denoted by  $\prod_{i=1}^n S_i$ .

The smallest positive singular value of a nonzero linear operator  $Q : \mathbb{R}^n \to \mathbb{R}^l$  is denoted by  $\sigma_Q^+$ . For a given closed convex set  $X \subset \mathbb{R}^n$ , its boundary is denoted by  $\partial X$  and the distance of a point  $x \in \mathbb{R}^n$  to X is denoted by  $\operatorname{dist}_X(x)$ . The indicator function of X at a point  $x \in \mathbb{R}^n$  is denoted by  $\delta_X(x)$  which has value 0 if  $x \in X$ and  $+\infty$  otherwise. For every z > 0 and positive integer b, we denote  $\log_b^+(z) :=$  $\max\{1, \lceil \log_b(z) \rceil\}$ .

139 The domain of a function  $h : \mathbb{R}^n \to (-\infty, \infty]$  is the set dom  $h := \{x \in \mathbb{R}^n : h(x) < +\infty\}$ . Moreover, h is said to be proper if dom  $h \neq \emptyset$ . The set of all lower 140 semi-continuous proper convex functions defined in  $\mathbb{R}^n$  is denoted by  $\overline{\text{Conv}} \mathbb{R}^n$ . The 142 set of functions in  $\overline{\text{Conv}} \mathbb{R}^n$  which have domain  $Z \subseteq \mathbb{R}^n$  is denoted by  $\overline{\text{Conv}} Z$ . The 143  $\varepsilon$ -subdifferential of a proper function  $h : \mathbb{R}^n \to (-\infty, \infty]$  is defined by

144 (1.9) 
$$\partial_{\varepsilon} h(z) := \{ u \in \mathbb{R}^n : h(z') \ge h(z) + \langle u, z' - z \rangle - \varepsilon, \quad \forall z' \in \mathbb{R}^n \}$$

for every  $z \in \mathbb{R}^n$ . The classic subdifferential, denoted by  $\partial h(\cdot)$ , corresponds to  $\partial_0 h(\cdot)$ . The normal cone of a closed convex set C at  $z \in C$ , denoted by  $N_C(z)$ , is defined as

147 
$$N_C(z) := \{ \xi \in \mathbb{R}^n : \langle \xi, u - z \rangle \le \varepsilon, \quad \forall u \in C \}.$$

If  $\psi$  is a real-valued function which is differentiable at  $\bar{z} \in \mathbb{R}^n$ , then its affine approximation  $\ell_{\psi}(\cdot, \bar{z})$  at  $\bar{z}$  is given by

150 (1.10) 
$$\ell_{\psi}(z;\bar{z}) := \psi(\bar{z}) + \langle \nabla \psi(\bar{z}), z - \bar{z} \rangle \quad \forall z \in \mathbb{R}^n.$$

151 If z = (x, y) then f(x, y) is equivalent to f(z) = f((x, y)).

152 Iterates of a scalar quantity have their iteration number appear as a subscript, e.g., 153  $c_{\ell}$ , while non-scalar quantities have this number appear as a superscript, e.g.,  $v^k$ , and 154  $\hat{p}^{\ell}$ . For variables with multiple blocks, the block number appears as a subscript, e.g., 155  $x_t^k$  and  $v_t^k$ . Finally, we define the following norm for any quantity  $u = (u_1, \ldots, u_B)$ 156 following a block structure as in (1.2):

157 (1.11) 
$$||u||_{\dagger} = ||(u_1, \dots, u_B)||_{\dagger} := \sum_{t=1}^{B} ||u_t||.$$

**2.** Alternating Direction Method of Multipliers. This section contains two subsections. The first one precisely describes the problem of interest and its underlying assumptions, while the second one presents the DP.ADMM and its corresponding iteration complexity.

162 **2.1. Problem of Interest.** This subsection presents the problem of interest and 163 the assumptions underlying it.

164 Denote the aggregated quantities

165 (2.1)  
166 
$$x_{\leq t} := (x_1, \dots, x_{t-1}), \quad x_{>t} := (x_{t+1}, \dots, x_B),$$

$$x_{\leq t} := (x_{\leq t}, x_t), \quad x_{\geq t} := (x_t, x_{>t}),$$

for every  $x = (x_1, \ldots, x_B) \in \mathcal{H}$ . Our problem of interest is finding approximate stationary points of (1.1) under the following assumptions:

(A1) for every t = 1, ..., B, we have  $h_t \in \overline{\text{Conv}} \mathbb{R}^{n_t}$  and  $\mathcal{H}_t := \text{dom } h_t$  is compact;

170 (A2)  $A \neq 0$  and  $\mathcal{F} := \{x \in \mathcal{H} : Ax = d\} \neq \emptyset$  where  $\mathcal{H} := \mathcal{H}_1 \times \cdots \times \mathcal{H}_B$ ;

(A3) h in (1.2) is  $K_h$ -Lipschitz continuous on  $\mathcal{H}$  for some  $K_h \ge 0$ ;

(A4) for every  $t = 1, \ldots, B$ , there exists  $m_t \ge 0$  such that

$$\begin{array}{cc} 173\\ 174 \end{array} (2.2) \qquad f(x_{< t}, \cdot, x_{> t}) + \delta_{\mathcal{H}_t}(\cdot) + \frac{m_t}{2} \|\cdot\|^2 \text{ is convex for all } x \in \mathcal{H}; \end{array}$$

(A5) f is differentiable on  $\mathcal{H}$  and, for every t = 1, ..., B - 1, there exists  $M_t \ge 0$ such that

$$\frac{1}{178} \qquad (2.3) \quad \|\nabla_{x_t} f(x_{\le t}, \tilde{x}_{>t}) - \nabla_{x_t} f(x_{\le t}, x_{>t})\| \le M_t \|\tilde{x}_{>t} - x_{>t}\| \quad \forall x, \tilde{x} \in \mathcal{H};$$

179 (A6) there exists  $z_{\dagger} \in \mathcal{F}$  such that  $d_{\dagger} := \operatorname{dist}_{\partial \mathcal{H}}(z_{\dagger}) > 0$ .

We now give a few remarks about the above assumptions. First, in view of the fact that  $\mathcal{H}$  is compact, the following scalars are bounded:

182 (2.4)  
$$D_{\dagger} := \sup_{z \in \mathcal{H}} \|z - z_{\dagger}\|, \quad G_{f} := \sup_{x \in \mathcal{H}} \|\nabla f(x)\|$$
$$\underline{\phi} := \inf_{x \in \mathcal{H}} \phi(x), \quad \overline{\phi} := \sup_{x \in \mathcal{H}} \phi(x).$$
5

183 Second, if f is a separable function, i.e., it is of the form  $f(z) = f_1(z_1) + \dots + f_B(z_B)$ , 184 then each  $M_t$  can be chosen to be zero. Third, any function h given by (1.2) such that

then each  $M_t$  can be chosen to be zero. Third, any function h given by (1.2) such that each  $h_t$  for t = 1, ..., B has the form  $h_t = \tilde{h}_t + \delta_{Z_t}$ , where  $\tilde{h}_t$  is a finite everywhere

Lipschitz continuous convex function and  $Z_t$  is a compact convex set, clearly satisfies

187 condition (A3) for some  $K_h$ .

For a given tolerance pair  $(\rho, \eta)$ , we define a  $(\rho, \eta)$ -stationary pair of (1.1) as being a pair  $(\bar{z}, \bar{q}) \in \mathcal{H} \times \mathbb{R}^{\ell}$  satisfying (1.8). It is well known that the first-order necessary condition for a point  $z \in \mathcal{H}$  to be a local minimum of (1.1) is that there exists  $q \in \mathbb{R}^{\ell}$ such that the stationary conditions

$$0 \in \nabla f(z) + A^*q + \partial h(z), \quad Az = d$$

hold. Hence, the requirements in (1.8) can be viewed as a direct relaxation of the
above stationary conditions. For ease of future reference, we consider the following
problem.

197

**Problem**  $S_{\rho,\eta}$ : Find a  $(\rho,\eta)$ -stationary pair  $(\bar{z},\bar{q})$  satisfying (1.8).

We now make three remarks about Problem  $S_{\rho,\eta}$ . First,  $(\bar{z}, \bar{q})$  is a solution of Problem  $S_{\rho,\eta}$  if and only if there exists a residual  $\bar{v} \in \mathbb{R}^n$  such that

200 (2.5) 
$$\bar{v} \in \nabla f(\bar{z}) + A^* \bar{q} + \partial h(\bar{z}), \quad \|\bar{v}\| \le \rho, \quad \|A\bar{z} - d\| \le \eta.$$

Second, condition (2.5) has been considered in many previous works (e.g., see [16, 17, 18, 19, 22]). Third, in the case where  $\|\cdot\| = \|\cdot\|_2$  and  $\rho = \eta$ , the stationarity condition in (1.8) implies the stationarity condition of the papers [15, 28] in Table 1.2. Specifically, [15, Definition 3.6] and [28, Definition 3.3] consider a pair  $(z,q) \in \mathcal{H} \times \mathbb{R}^{\ell}$ to be an  $\varepsilon$ -stationary pair if it satisfies

206 
$$\operatorname{dist}(0, \nabla_{z_t} f(z_1, \dots, z_B) + A_t^* q + \partial h_t(z_t)) \leq \varepsilon, \quad ||Az - d|| \leq \varepsilon,$$

207 for every t = 1, ..., B.

In the following subsection, we present a method (Algorithm 2.1) that computes a triple  $(\bar{z}, \bar{q}, \bar{v})$  satisfying (2.5), and hence which guarantees that  $(\bar{z}, \bar{q})$  is a solution of Problem  $S_{\rho,\eta}$ .

211 **2.2. DP.ADMM.** We present DP.ADMM in two parts. The first part presents 212 a static version of DP.ADMM which either (i) stops with a solution of Problem  $S_{\rho,\eta}$ 213 or (ii) signals that its penalty parameter is too small. The second part presents the 214 (dynamic) DP.ADMM that repeatedly invokes the static version on an increasing 215 sequence of penalty parameters.

Both versions of DP.ADMM make use of the following condition on  $(\chi, \theta)$ :

217 (2.6) 
$$2\chi B(2-\theta)(1-\theta) \le \theta^2, \quad (\chi,\theta) \in (0,1]^2.$$

For ease of reference and discussion, the pseudocode for the static DP.ADMM is given in Algorithm 2.1 below. Notice that the classic proximal ADMM iteration

220 
$$x_{t}^{k} = \underset{u^{t} \in \mathbb{R}^{n_{t}}}{\operatorname{argmin}} \left\{ \lambda \mathcal{L}_{c}^{0}(x_{< t}^{k}, u_{t}, x_{> t}^{k-1}; p^{k-1}) + \frac{1}{2} \|u_{t} - x_{t}^{k-1}\|^{2} \right\}, \quad t = 1, \dots, B,$$
221 
$$p^{k} = p^{k-1} + c \left(Ax^{k} - d\right),$$

Algorithm 2.1 Static DP.ADMM

Input:  $x^0 \in \mathcal{H}, p^0 \in A(\mathbb{R}^n), \lambda \in (0, 1/(2m)], c > 0;$ Require: m as in (2.7),  $(\rho, \eta) \in \mathbb{R}^2_{++}$ ,  $(\chi, \theta)$  as in (2.6) 1: for  $k \leftarrow 1, 2, ...$  do STEP 1 (prox update): for  $t \leftarrow 1, 2, \ldots, B$  do 2:  $x_t^k \leftarrow \operatorname{argmin}_{u_t \in \mathbb{R}^{n_t}} \left\{ \lambda \mathcal{L}_c^{\theta}(x_{< t}^k, u_t, x_{> t}^{k-1}; p^{k-1}) + \frac{1}{2} \| u_t - x_t^{k-1} \|^2 \right\}$ 3:  $q^k \leftarrow (1-\theta)p^{k-1} + c(Ax^k - d)$ 4: STEP 2a (successful termination check): for  $t \leftarrow 1, 2, \ldots, B$  do 5: $\begin{array}{l} v_t^k \leftarrow \nabla_{x_t} f(x_{\leq t}^k, x_{>t}^k) - \nabla_{x_t} f(x_{\leq t}^k, x_{>t}^{k-1}) \\ v_t^k \leftarrow \delta_t^k + cA_t^k \sum_{s=t+1}^B A_s(x_s^k - x_s^{k-1}) - \frac{1}{\lambda} (x_t^k - x_t^{k-1}) \end{array}$ 6:7: $\begin{array}{l} \mbox{if } \|v^k\| \leq \rho \ \ \mbox{and } \|Ax^k - d\| \leq \eta \ \mbox{then} \\ \ \ \mbox{return } (x^k, p^k, q^k, v^k) \end{array}$ 8: 9: STEP 2b (unsuccessful termination check): if  $k \equiv 0 \mod 2$  and  $k \ge 3$  then 10:
$$\begin{split} & \mathcal{S}_{k}^{(v)} \leftarrow \frac{2}{k+2} \sum_{i=k/2}^{k} \|v^{i}\| \\ & \mathcal{S}_{k}^{(f)} \leftarrow \frac{2}{k+2} \sum_{i=k/2}^{k} \|Ax^{i} - d\| \\ & \text{if } \frac{1}{\rho} \cdot \mathcal{S}_{k}^{(v)} + \frac{1}{\eta} \sqrt{\frac{c^{3}}{k}} \cdot \mathcal{S}_{k}^{(f)} \leq 1 \text{ then} \end{split}$$
11: 12: 13:**return**  $(x^k, p^k, q^k, v^k)$ 14: STEP 3 (multiplier update):  $p^k \leftarrow (1-\theta)p^{\hat{k}-1} + \chi c(Ax^k - d)$ 15:

222

223	corresponds to the case of $(\chi, \theta) = (1, 0)$ , where $c \ge 1$ is a fixed penalty parameter.
224	The next result describes the iteration complexity and some useful technical prop-
225	erties of Algorithm 2.1. Its proof is given in Section 3.3, and it uses three sets of scalars.

The first set is independent of  $(c, p^0)$  and is given by 226

$$M := \max_{1 \le t \le B} M_t, \quad m := \max_{1 \le t \le B} m_t, \quad \Delta_\phi := \overline{\phi} - \underline{\phi}, \quad \kappa_0 := \frac{2B^2 \left(\lambda M + 1\right)}{\sqrt{\lambda}},$$
227 (2.7) 
$$\kappa_1 := \frac{\chi \|A\| D_{\dagger}}{\theta}, \quad \kappa_2 := \frac{1}{\theta} \left[ 1 + \frac{2\chi D_{\dagger} (K_h + G_f)}{\theta d_{\dagger} \sigma_A^+} \right] + 1,$$

$$\kappa_3 := \frac{108\kappa_2^2}{\chi^2}, \quad \kappa_4 := \frac{\theta d_{\dagger}\sigma_A^+}{\chi D_{\dagger}}, \quad \kappa_5 := 8(B-1) \|A\|_{\dagger}^2, \quad \kappa_6 := 3 + \frac{8\kappa_0^2 \Delta_{\phi}}{\kappa_4^2}.$$

228

where  $(G_f, D_{\dagger}, \overline{\phi}, \phi)$ ,  $K_h$ , and  $(m_t, M_t)$  are as in (2.4), (A3), and (A4). The second 229 set is dependent on a given lower bound  $\underline{c}$  on c and is given by 230

231 (2.8) 
$$\tilde{\kappa}_{\underline{c}}^{(0)} := 2\left(\sqrt{\Delta_{\phi}} + \frac{5\kappa_2}{\chi\sqrt{\underline{c}}}\right), \quad \tilde{\kappa}_{\underline{c}}^{(1)} := 3\kappa_5[\tilde{\kappa}_{\underline{c}}^{(0)}]^2, \quad \tilde{\kappa}_{\underline{c}}^{(2)} := 3\kappa_0^2[\tilde{\kappa}_{\underline{c}}^{(0)}]^2.$$

233 The third set is dependent on a given upper bound  $\mathcal{R}$  on  $||p^0||/c$  and is given by

$$\xi_{\mathcal{R}}^{(0)} := \frac{8}{\kappa_4^2} \left[ \frac{9\kappa_0^2(\mathcal{R} + \kappa_1)^2}{\chi^2} + \kappa_5 \Delta_\phi \right] + (1 - \theta)(\mathcal{R} + \kappa_1),$$

234 (2.9)

$$\xi_{\mathcal{R}}^{(1)} := \frac{72\kappa_5(\mathcal{R}+\kappa_1)^2}{\chi^2\kappa_4^2}.$$

 $235 \\ 236$ 

242 243

237 PROPOSITION 2.1. Let  $\mathcal{R} \ge 0$  and  $\underline{c} > 0$  be given, and assume that the pair  $(c, p^0)$ 238 given to Algorithm 2.1 satisfies

$$||p_0|| \le c\mathcal{R}, \quad c \ge \underline{c}.$$

240 Then, the following statements hold about the call to Algorithm 2.1:

241 (a) it terminates in a number of iterations bounded by

$$\mathcal{T}_c(\rho,\eta \,|\,\underline{c},\mathcal{R}) := 48 \left( \left\{ \kappa_6 + \frac{\tilde{\kappa}_c^{(1)}}{\rho^2} \right\} + \left\{ \xi_{\mathcal{R}}^{(0)} + \frac{\kappa_3}{\eta^2} + \frac{\tilde{\kappa}_c^{(2)}}{\rho^2} \right\} c + \xi_{\mathcal{R}}^{(1)} c^2 \right),$$

244 where  $(\kappa_3, \kappa_6)$ ,  $(\tilde{\kappa}_{\underline{c}}^{(1)}, \tilde{\kappa}_{\underline{c}}^{(2)})$ , and  $(\xi_{\mathcal{R}}^{(0)}, \xi_{\mathcal{R}}^{(1)})$  are as in (2.7), (2.8), and (2.9), 245 respectively;

246 (b) if it terminates successfully in Step 2a, then the first and third components of 247 its output quadruple  $(\bar{z}, \bar{p}, \bar{q}, \bar{v})$  solve Problem  $S_{\rho,\eta}$ ;

(c) if c satisfies

249 (2.12) 
$$c \ge \hat{c}(\rho, \eta \mid \underline{c}, \mathcal{R}) := \frac{1}{\underline{c}^2} \left[ \mathcal{T}_{\underline{c}}(1, 1 \mid \underline{c}, \mathcal{R}) + \frac{\sqrt{\underline{c}^3 \cdot \mathcal{T}_{\underline{c}}(1, 1 \mid \underline{c}, \mathcal{R})}}{\min\{\rho, \eta\}} \right]$$

250 where  $\mathcal{T}_c(\rho, \eta | \underline{c}, \mathcal{R})$  is as in (a), then it must terminate successfully.

We now make some remarks about Proposition 2.1. First, statement (c) implies that Algorithm 2.1 terminates successfully if its penalty parameter c is sufficiently large, i.e.,  $c = \Omega(\varepsilon^{-1})$  where  $\varepsilon := \min\{\rho, \eta\}$ . Moreover, if a penalty parameter csatisfying (2.12) and the condition that  $c = \mathcal{O}(\varepsilon^{-1})$  is known, then it follows from Proposition 2.1(a) that the iteration complexity of Algorithm 2.1 for finding a solution of Problem  $S_{\rho,\eta}$  is  $\mathcal{O}(\varepsilon^{-3})$ .

Since a penalty parameter c as in the above paragraph is nearly impossible to compute, we next present an adaptive method, namely, Algorithm 2.2 below, which adaptively increases the penalty parameter c, and whose overall number of iterations is also  $\mathcal{O}(\varepsilon^{-3})$ .

Some comments about Algorithm 2.2 are in order. First, it employs a "warm-261 start" type strategy for calling Algorithm 2.1 at each iteration  $\ell$ . Specifically, the 262input of the  $\ell^{\text{th}}$  to Algorithm 2.1 is the pair  $(\bar{z}^{\ell-1}, \bar{p}^{\ell-1})$  output by the previous call 263 to Algorithm 2.1. Second, the initial penalty parameter  $c_1$  can be chosen to be any 264positive scalar, in contrast to many of the methods listed in Section 1 where this 265parameter must be chosen sufficiently large. Third, the initial point  $\bar{z}^0$  only needs to 266be in the domain of h and need not be feasible or near feasible. Finally, while the 267initial Lagrange multiplier  $\bar{p}^0$  is chosen to be zero, the analysis in this paper can be 268 carried out for any  $\bar{p}^0 \in A(\mathbb{R}^n)$ , at the cost of more complicated complexity bounds. 269

The next result, whose proof is given in Section 4, gives the complexity of Algorithm 2.2 in terms of the total number of iterations of Algorithm 2.1 across all of its calls.

## Algorithm 2.2 DP.ADMM

6:  $c_{\ell+1} \leftarrow 2c_{\ell}$ 

273 THEOREM 2.2. Define the scalars

274 (2.13) 
$$T_1 := \mathcal{T}_{c_1}(1, 1 | c_1, 2\kappa_1), \quad \varepsilon := \min\{\rho, \eta\},$$

where  $\kappa_1$  and  $\mathcal{T}_c(\cdot, \cdot | \cdot, \cdot)$  are as in (2.7) and (2.11), respectively. Then, Algorithm 2.2 stops and outputs a pair that solves Problem  $S_{\rho,\eta}$  in a number of iterations of Algorithm 2.1 bounded by

278 (2.14) 
$$T_1\left(2E_0^2 + \frac{E_0 + 2E_1^2}{\varepsilon^2} + \frac{E_1}{\varepsilon^3}\right)$$

280 where

281 (2.15) 
$$E_0 := 2\left(1 + \frac{T_1^2}{c_1^3}\right), \quad E_1 := 2\sqrt{\frac{T_1}{c_1^3}}.$$

Since  $T_1 = \mathcal{O}(c_1^{-1})$  in view of (2.11) and (2.13), it follows from (2.14) and (2.15) that if  $c_1^{-1} = \mathcal{O}(1)$ , then the overall complexity of Algorithm 2.2 is  $\mathcal{O}(\varepsilon^{-3})$ .

**3.** Analysis of Algorithm 2.1. This section presents the main properties of Algorithm 2.1, and it contains three subsections. More specifically, the first (resp., second) subsection establishes some key bounds on the ergodic means of the sequences  $\{\|v^k\|\}_{k\geq 0}$  and  $\{\|Ax^k - d\|\}_{k\geq 0}$  (resp., the sequence  $\{\|p_k\|\}_{k\geq 0}$ ). The third one proves Proposition 2.1.

Throughout this section, we let  $\{(v^i, x^i, p^i, q^i)\}_{i=1}^k$  denote the iterates generated by Algorithm 2.1 up to and including the  $k^{\text{th}}$  iteration for some  $k \geq 3$ . Moreover, for every  $i \geq 1$  and  $(\chi, \theta) \in \mathbb{R}^2_{++}$  satisfying (2.6), we make use of the following useful constants and shorthand notation

$$a_{\theta} = \theta(1-\theta), \quad b_{\theta} := (2-\theta)(1-\theta),$$

$$\gamma_{\theta} := \frac{(1-2B\chi b_{\theta}) - (1-\theta)^2}{2\chi}, \quad f^i := Ax^i - d,$$

294 the aggregated quantities in (2.1), and the averaged quantities

295 (3.2) 
$$S_{j,k}^{(p)} := \frac{\sum_{i=j}^{k} \|p^{i}\|}{k-j+1}, \quad S_{j,k}^{(v)} := \frac{\sum_{i=j}^{k} \|v^{i}\|}{k-j+1}, \quad S_{j,k}^{(f)} := \frac{\sum_{i=j}^{k} \|f^{i}\|}{k-j+1}.$$

for every j = 1, ..., k. Notice that  $\gamma_{\theta} \ge \theta/\chi$  in view of (2.6). We also denote  $\Delta y^i$  to be the difference of iterates for any variable y at iteration i, i.e.,

299 (3.3) 
$$\Delta y^i \equiv y^i - y^{i-1}.$$

3.1. Properties of the Key Residuals. This subsection presents bounds on 300 the residuals  $\{\|v^i\|\}_{i=2}^k$  and  $\{\|f^i\|\}_{i=2}^k$  generated by Algorithm 2.1. These bounds will 301 be particularly helpful for proving Proposition 2.1 in Subsection 3.3. 302

The first result presents some key properties about the generated iterates. 303

LEMMA 3.1. For i = 1, ..., k, 304

305

(a)  $f^{i} = [p^{i} - (1 - \theta)p^{i-1}] / (\chi c);$ (b)  $v^{i} \in \nabla f(x^{i}) + A^{*}q^{i} + \partial h(x^{i})$  and 306

307 (3.4) 
$$\|v^i\| \le B\left(M + \frac{1}{\lambda}\right) \|\Delta x^i\|_{\dagger} + c\|A\|_{\dagger} \sum_{t=2}^B \|A_t \Delta x_t^i\|,$$

where  $\|\cdot\|_{\dagger}$  is as in (1.11). 308

*Proof.* (a) This is immediate from step 3 of Algorithm 2.1 and the definition of 309  $f^i$  in (3.1). 310

(b) We first prove the required inclusion. The optimality of  $x_t^k$  in Step 1 of 311 Algorithm 2.1, and assumption (A4), imply that 312

313 
$$0 \in \partial \left[ \mathcal{L}_{c}^{\theta}(x_{< t}^{i}, \cdot, x_{> t}^{i-1}; p^{i-1}) + \frac{1}{2\lambda} \| \cdot - x_{k}^{i-1} \|^{2} \right] (x^{i})$$

314 
$$= \nabla_{x_t} f(x_{\leq t}^i, x_{>t}^{i-1}) + A_t^* \left[ (1-\theta) p^{i-1} + c[A(x_{\leq t}^i, x_{>t}^{i-1}) - d] \right] + \partial h_t(x_t^i) + \frac{1}{\lambda} \Delta x_t^i$$

315 
$$= \nabla_{x_t} f(x_{\leq t}^i, x_{>t}^{i-1}) + A_t^* \left( q^i - c \sum_{s=t+1}^{-\infty} A_s \Delta x_s^i \right) + \partial h_t(x_t^i) + \frac{1}{\lambda} \Delta x_t^i$$

for every  $1 \le t \le B$ . Hence, the inclusion holds. To show the inequality, let  $1 \le t \le B$ 318 319 be fixed and use the triangle inequality, the definition of  $v_t^i$ , and assumption (A5) to obtain 320

321 
$$\|v_t^i\| \le \|\nabla_{x_t} f(x_{\le t}^i, x_{>t}^i) - \nabla_{x_t} f(x_{\le t}^i, x_{>t}^{i-1})\| + c \sum_{s=t+1}^B \|A_t^* A_s \Delta x_s^i\| + \frac{1}{\lambda} \|\Delta x_t^i\|$$

322 
$$\leq M_t \|x_{>t}^i - x_{>t}^{i-1}\| + c\|A_t\| \sum_{s=t+1}^B \|A_s \Delta x_s^i\| + \frac{1}{\lambda} \|\Delta x_t^i\|$$

323  
324 
$$\leq \left(M + \frac{1}{\lambda}\right) \sum_{s=t}^{B} \|\Delta x_{s}^{i}\| + c\|A_{t}\| \sum_{t=2}^{B} \|A_{t}\Delta x_{t}^{i}\|.$$

Summing the above bound from t = 1 to B, and using the definition of M in (2.7) 325 and the triangle inequality, we conclude that 326

327 
$$\|v^{i}\| \leq \sum_{t=1}^{B} \|v^{i}_{t}\| \leq \left(M + \frac{1}{\lambda}\right) \sum_{t=1}^{B} \sum_{s=t}^{B} \|\Delta x^{i}_{s}\| + c\|A\|_{\dagger} \sum_{t=2}^{B} \|A_{t}\Delta x^{i}_{t}\|$$

$$\leq B\left(M + \frac{1}{\lambda}\right) \|\Delta x^i\|_{\dagger} + c\|A\|_{\dagger} \sum_{t=2}^{D} \|A_t \Delta x_t^i\|.$$

Notice that part (b) of the above result implies that  $(\bar{x}, \bar{v}, \bar{p}) = (x^i, v^i, q^i)$  satisfies 330 331 the inclusion in (2.5). Hence, if  $||v^i||$  and  $||f^i||$  are sufficiently small at some iteration

i, then Algorithm 2.1 clearly returns a solution of Problem  $S_{\rho,\eta}$  at iteration i, i.e., 332 Proposition 2.1(b) holds. However, to understand when Algorithm 2.1 terminates, we 333 334 will need to develop more refined bounds on  $||v_i||$  and  $||f_i||$ .

To begin, we present some relations between the perturbed augmented Lagrangian 335  $\mathcal{L}_{c}^{\theta}(\cdot;\cdot)$  and the iterates  $\{(x^{i},p^{i})\}_{i=1}^{k}$ . For conciseness, its proof is given in Appendix A. 336

LEMMA 3.2. For i = 1, ..., k, 337

338 (a) 
$$\mathcal{L}_{c}^{\theta}(x^{i};p^{i}) - \mathcal{L}_{c}^{\theta}(x^{i};p^{i-1}) = b_{\theta} \|\Delta p^{i}\|^{2} / (2\chi c) + a_{\theta} \left( \|p^{i}\|^{2} - \|p^{i-1}\|^{2} \right) / (2\chi c);$$

(b)  $\mathcal{L}_{c}^{\theta}(x^{i};p^{i-1}) - \mathcal{L}_{c}^{\theta}(x^{i-1};p^{i-1}) \leq -\|\Delta x^{i}\|^{2}/(2\lambda) - c\sum_{t=1}^{B}\|A_{t}\Delta x_{t}^{i}\|^{2}/2;$ (c) if  $i \geq 2$ , it holds that 339

340

341 (3.5) 
$$\frac{b_{\theta}}{2\chi c} \|\Delta p^{i}\|^{2} - \frac{c}{4} \sum_{t=1}^{B} \|A_{t} \Delta x_{t}^{i}\|^{2} \le \frac{\gamma_{\theta}}{4B\chi c} \left( \|\Delta p^{i-1}\|^{2} - \|\Delta p^{i}\|^{2} \right).$$

The next result uses the above relations to establish a bound on the quantities in 342 343the right-hand-side of (3.4).

LEMMA 3.3. For j = 1, ..., k, 344

345 (3.6) 
$$\sum_{i=j+1}^{\kappa} \|v^i\|^2 \le (\kappa_0^2 + \kappa_5 c) \left[\Psi_j(c) - \Psi_k(c)\right],$$

where  $(\kappa_0, \kappa_5)$  is as in (2.7), and denoting  $(a_{\theta}, \gamma_{\theta})$  and as in (3.1), we have 347

348 (3.7) 
$$\Psi_i(c) := \mathcal{L}_c^{\theta}(x^i; p^i) - \frac{a_{\theta}}{2\chi c} \|p^i\|^2 + \frac{\gamma_{\theta}}{4B\chi c} \|\Delta p^i\|^2 \quad \forall i \ge 1.$$

*Proof.* Using the inequality  $||z||_1^2 \le n ||z||_2^2$  for  $z \in \mathbb{R}^n$  and (3.4), we first have that 350

351 
$$\sum_{i=j+1}^{k} \|v^{i}\|^{2} \stackrel{(3.4)}{\leq} \sum_{i=j+1}^{k} \left[ B\left(M + \frac{1}{\lambda}\right) \|\Delta x^{i}\|_{\dagger} + c\|A\|_{\dagger} \sum_{t=2}^{B} \|A_{t}\Delta x_{t}^{i}\| \right]^{2}$$

352

$$\leq \sum_{i=j+1}^{N} 2B^{2} \left( M + \frac{1}{\lambda} \right)^{2} \|\Delta x^{i}\|_{\dagger}^{2} + c^{2} \|A\|_{\dagger}^{2} \left( \sum_{t=2}^{D} \|A_{t} \Delta x_{t}^{i}\| \right)$$

$$\leq \sum_{i=j+1}^{k} 2B^{4} \left( M + \frac{1}{\lambda} \right)^{2} \|\Delta x^{i}\|^{2} + 2(B-1)c^{2} \|A\|_{\dagger}^{2} \sum_{t=2}^{B} \|A_{t} \Delta x_{t}^{i}\|^{2}$$

$$\leq \sum_{i=j+1}^{353} 2B^4 \left( M + \frac{1}{\lambda} \right) \|\Delta x^i\|^2 + 2(B-1)c^2 \|A\|_{\dagger}^2 \sum_{t=2}^{3} \|A_{t}\|_{\bullet}^{2}$$

354 (3.8) 
$$\leq (\kappa_0^2 + \kappa_5 c) \sum_{i=j+1}^n \left[ \frac{1}{2\lambda} \|\Delta x^i\| + \frac{c}{4} \sum_{t=2}^n \|A_t \Delta x_t^i\|^2 \right]$$

Combining Lemma 3.2(a)–(c), the definition of  $\Psi^i_{\theta}$ , and the bound  $(a+b)^2 \leq 2a^2+2b^2$ 356for  $a, b \in \mathbb{R}_+$ , we also have that 357

358 
$$\frac{1}{2\lambda} \|\Delta x^i\|^2 + \frac{c}{4} \sum_{t=2}^B \|A_t \Delta x^i\|^2$$

9 
$$\sum_{j=1}^{\text{L.3.2(a)-(b)}} \mathcal{L}_{c}^{\theta}(x^{j-1}; p^{j-1}) - \mathcal{L}_{c}^{\theta}(x^{j}; p^{j}) + \frac{a_{\theta}}{2\chi c} \Delta_{p,j}^{(2)} + \frac{b_{\theta}}{2\chi c} \|\Delta p^{i}\|^{2} - \frac{c}{4} \sum_{t=1}^{B} \|A_{t} \Delta x_{t}^{i}\|^{2}$$

360 
$$\overset{\text{L.3.2(c)}}{\leq} \mathcal{L}_{c}^{\theta}(x^{j-1}; p^{j-1}) - \mathcal{L}_{c}^{\theta}(x^{j}; p^{j}) + \frac{a_{\theta}}{2\chi c} \Delta_{p,j}^{(2)} + \frac{\gamma_{\theta}}{4B\chi c} \left( \|\Delta p^{i-1}\|^{2} - \|\Delta p^{i}\|^{2} \right)$$

## This manuscript is for review purposes only.

$$361 = \Psi_{i-1}(c) - \Psi_i(c),$$

where  $\Delta_{p,j}^{(2)} := \|p^j\|^2 - \|p^{j-1}\|^2$ . Consequently, summing the above inequality from i = j + 1 to k, and combining the resulting inequality with (3.8), yields the desired bound.

We now bound the quantity on the right-hand-side of (3.6)

367 LEMMA 3.4. For any  $j \ge 1$  and  $k \ge 1$ ,

368 (a) 
$$\mathcal{L}^{\theta}_{c}(x^{j};p^{j}) \leq \phi(x^{j}) + 3(\|p^{j}\|^{2} + \|p^{j-1}\|^{2})/(\chi^{2}c),$$

369 (b) 
$$\mathcal{L}_{c}^{\bar{\theta}}(x^{k};p^{k}) \ge \phi(x^{k}) - \|p^{k}\|^{2}/(2c);$$

(c) it holds that

371 (3.9) 
$$\Psi_j(c) - \Psi_k(c) \le \Delta_\phi + 4\left(\frac{\|p^j\|^2 + \|p^{j-1}\|^2 + \|p^k\|^2}{\chi^2 c}\right),$$

372 where  $\Psi_i(\cdot)$  and  $\Delta_{\phi}$  are as in (3.6) and (2.7), respectively.

373 Proof. (a)–(b) See Appendix A.

(c) Using parts (a)–(b), the fact that  $a_{\theta} \in (0,1)$  and  $(\chi,\theta) \in (0,1)^2$ , the relation (a + b)<sup>2</sup>  $\leq 2a^2 + 2b^2$  for  $a, b \in \mathbb{R}_+$ , and the bound  $\gamma_{\theta} \leq 1/(2\chi)$ , it holds that

376 
$$\Psi_j(c) - \Psi_k(c)$$

377 
$$= \left[\mathcal{L}_{c}^{\theta}(x^{j};p^{j}) - \mathcal{L}_{c}^{\theta}(x^{k};p^{k})\right] + \frac{a_{\theta}(\|p^{k}\|^{2} - \|p^{j}\|^{2})}{2\chi c} + \frac{\gamma_{\theta}(\|\Delta p^{j}\|^{2} - \|\Delta p^{k}\|^{2})}{4B\chi c}$$

378 
$$\leq \left[\mathcal{L}_c^{\theta}(x^j; p^j) - \mathcal{L}_c^{\theta}(x^k; p^k)\right] + \frac{a_{\theta} \|p^k\|^2}{2\chi c} + \frac{\gamma_{\theta} \|\Delta p^j\|^2}{4B\chi c}$$

379 
$$\leq \left[\mathcal{L}_{c}^{\theta}(x^{j};p^{j}) - \mathcal{L}_{c}^{\theta}(x^{k};p^{k})\right] + \frac{\|p^{k}\|^{2}}{2\chi c} + \frac{\|p^{j-1}\|^{2} + \|p^{j}\|^{2}}{4B\chi^{2}c}$$

380 
$$\stackrel{(\mathbf{a})-(\mathbf{b})}{\leq} \left[ \phi(x^{j}) - \phi(x^{k}) + \frac{3(\|p^{j}\|^{2} + \|p^{j-1}\|^{2})}{\chi^{2}c} + \frac{\|p^{k}\|^{2}}{2c} \right] +$$

$$\frac{\|p^k\|^2}{381} \qquad \qquad \frac{\|p^k\|^2}{2\chi c} + \frac{\|p^{j-1}\|^2 + \|p^j\|^2}{4B\chi^2 c} \le \Delta_{\phi} + 4\left(\frac{\|p^j\|^2 + \|p^{j-1}\|^2 + \|p^k\|^2}{\chi^2 c}\right). \qquad \square$$

The next result presents bounds on  $S_{j+1,k}^{(f)}$  and  $S_{j+1,k}^{(v)}$ . PROPOSITION 3.5. For j = 1, ..., k - 1,

385 (3.10) 
$$S_{j+1,k}^{(f)} \le \frac{\|p^j\| + 2S_{j+1,k}^{(p)}}{\chi c},$$

$$S_{j+1,k}^{(v)} \leq 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}} \left( \Delta_{\phi}^{1/2} + \frac{\|p^j\| + \|p^{j-1}\| + \|p^k\|}{\chi\sqrt{c}} \right),$$

388 where  $(\kappa_0, \kappa_5, \Delta_{\phi})$  is as in (2.7).

389 Proof. Using Lemma 3.1(a), the fact that  $\theta \in (0, 1)$ , and the triangle inequality, 390 it holds that

$$S_{j+1,k}^{(f)} = \frac{\sum_{i=j+1}^{k} \|p^{i} - (1-\theta)p^{i-1}\|}{\chi c(k-j)} \le \frac{\sum_{i=j+1}^{k} (\|p^{i-1}\| + \|p^{i}\|)}{\chi c(k-j)} \le \frac{\|p^{j}\| + 2S_{j+1,k}^{(p)}}{\chi c}$$

which is (3.10). On the other hand, to show (3.11), we use the definition of  $S_{j+1,k}^{(v)}$ , the fact that  $\sqrt{a+b} \leq \sqrt{a} + \sqrt{b}$  for  $a, b \in \mathbb{R}_+$ , Lemma 3.3, and Lemma 3.4(c), to conclude that

396 
$$S_{j+1,k}^{(v)} = \frac{\sum_{i=j+1}^{k} \|v^{i}\|}{k-j} \le \left(\frac{\sum_{i=j+1}^{k} \|v^{i}\|^{2}}{k-j}\right)^{1/2}$$
L.3.3  $\left([\kappa_{i}^{2} + \kappa_{i}c][\Psi_{i}(c) - \Psi_{i}(c)]\right)^{1/2}$ 

397

398

$$\stackrel{\text{L.3.4}(c)}{\leq} \sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k - j}} \left[ \Delta_{\phi} + 4 \left( \frac{\|p^j\|^2 + \|p^{j-1}\|^2 + \|p^k\|^2}{\chi^2 c} \right) \right]^{1/2}$$

$$\begin{cases} 399\\ 400 \end{cases} (3.12) \leq 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k - j}} \left(\Delta_{\phi}^{1/2} + \frac{\|p^j\| + \|p^{j-1}\| + \|p^k\|}{\chi\sqrt{c}}\right). \end{cases}$$

401 Observe that both residuals  $S_{j+1,k}^{(v)}$  and  $S_{j+1,k}^{(f)}$  depend on the size of the Lagrange 402 multipliers  $p^j$ ,  $p^{j-1}$ , and  $p^k$ . If all the multipliers generated by Algorithm 2.1 could be 403 shown to be bounded independent of c then it would be easy to see that (3.10)-(3.11)404 with j = 1 and some  $c = \Theta(\eta^{-1})$  would imply the existence of some  $k = O(\eta^{-1}\rho^{-2})$ 405 such that  $[S_{2,k}^{(v)}/\rho] + [S_{2,k}^{(f)}/\eta] \leq 1$ . Consequently, Algorithm 2.1 would find a solution 406 of Problem  $S_{\rho,\eta}$  in  $O(\eta^{-1}\rho^{-2})$  iterations.

Unfortunately, we do not know how to bound  $\{||p_i||\}$  independent of c, so we will instead show the existence of  $1 \leq j \leq k$  such that (i) indices j and k-j are  $\Theta(\eta^{-1}\rho^{-2})$  and (ii) the three multipliers  $p^j$ ,  $p^{j-1}$ , and  $p^k$  are bounded. This fact and Proposition 3.5 suffice to show that the last (hypothetical) conclusion in the previous paragraph actually holds.

412 **3.2. Bounding the Lagrange Multipliers.** This subsection generalizes the 413 analysis in [19]. More specifically, Proposition 3.8 shows that if k is sufficiently large 414 relative to an index j, the penalty parameter c, and  $||p^0||$ , then  $S_{j+1,k}^{(p)} = \mathcal{O}(1)$ . 415 The proof of the first result can be found in [26, Lemma B.3] using the variable

The proof of the first result can be found in [26, Lemma B.3] using the variable substitution  $(q, q^-, \chi) = (q^i, [1 - \theta]p^{i-1}, c)$  and step 4 of Algorithm 2.1.

417 LEMMA 3.6. For every  $i \ge 1$  and  $r \in \partial h(z^i) + A^*q^i$ , it holds that

418 
$$\|q^i\| \le \max\left\{ (1-\theta) \|p^{i-1}\|, \frac{2D_{\dagger}(K_h + \|r\|)}{d_{\ddagger}\sigma_A^+} \right\}.$$

419 The next result presents some fundamental properties about  $p^{i-1}$ ,  $p^i$ , and  $q^i$ .

420 LEMMA 3.7. For every 
$$1 \le j \le k$$
,  
421 (a)  $p^j = \chi q^j + (1 - \chi)(1 - \theta)p^{j-1}$ ;  
422 (b)  $\|p^j\| \le \|p^0\| + \kappa_1 c$ ;

423 (c) it holds that

$$\frac{(1-\theta)\|p^k\|}{k-j} + \theta S_{j+1,k}^{(p)} \le \frac{(1-\theta)\|p^j\|}{k-j} + \frac{2\chi D_{\dagger} \left[K_h + G_f + S_{j+1,k}^{(v)}\right]}{d_{\dagger}\sigma_A^+},$$

where  $K_h$ ,  $d_{\dagger}$ , and  $(D_{\dagger}, G_f)$  are as in (A3), (A6), and (2.4), respectively.

*Proof.* (a) This is an immediate consequence of the updates for  $p^{j}$  and  $q^{j}$  in 426 Algorithm 2.1. 427

(b) In view of Step 3 of Algorithm 2.1, the fact that  $\theta \in (0, 1)$ , and the triangle 428 inequality, it holds that 429

430 
$$||p^{j}|| \le (1-\theta)||p^{j-1}|| + \chi c||f^{j}|| \le (1-\theta)^{j}||p^{0}|| + \chi c \sum_{i=0}^{j-1} (1-\theta)^{i}||f^{i}||$$

$$\leq \|p^{0}\| + \chi c \|A\| \sup_{z \in \mathcal{H}} \|z - z_{\dagger}\| \sum_{i=0}^{\infty} (1 - \theta)$$

$$= \|p^0\| + \frac{\chi c \|A\| D_{\dagger}}{\theta} = \|p^0\| + \kappa_1 c.$$

(c) Let  $i \ge 1$  be fixed, define 434

435 
$$d_{\chi,\theta} := (1-\theta)(1-\chi)$$

and recall that Lemma 3.1(b) implies  $v^i - \nabla f(x^i) \in \partial h(x^i) + A^*q^i$ . Using Lemma 3.6 436 with  $r = v^i - \nabla f(x^i)$ , the definition of  $G_f$  in (2.4), and part (a), we first have that 437

438 
$$\|p^{i}\| \stackrel{(a)}{=} \|\chi q^{i} + d_{\chi,\theta} \cdot p^{i-1}\| \leq \chi \|q^{i}\| + d_{\chi,\theta} \|p^{i-1}\|$$
  
439 
$$\stackrel{\text{L.3.6}}{\leq} d_{\chi,\theta} \|p^{i-1}\| + \chi \max\left\{ (1-\theta)\|p^{i-1}\|, \frac{2D_{\dagger}(K_{h} + \|v^{i} - \nabla f(x^{i})\|)}{d_{\dagger}\sigma_{A}^{+}} \right\}$$

440 
$$\leq (1-\theta)(1-\chi)\|p^{i-1}\| + \chi \left[ (1-\theta)\|p^{i-1}\| + \frac{2D_{\dagger}(K_h + \|v^i - \nabla f(x^i)\|)}{d_{\dagger}\sigma_A^+} \right]$$

441 
$$\leq (1-\theta) \|p^{i-1}\| + \frac{2\chi D_{\dagger}(K_h + \|\nabla f(x^i)\| + \|v^i\|)}{d_{\dagger}\sigma_A^+}$$

442  
443 
$$\leq (1-\theta) \|p^{i-1}\| + \frac{2\chi D_{\dagger}(K_h + G_f + \|v^i\|)}{d_{\dagger}\sigma_A^+}.$$

Summing the above inequality from i = j + 1 to k and dividing by k - j yields the 444 desired conclusion. 445Π

We are now ready to present the claimed bound on  $S_{j+1,k}^{(p)}$ . 446

PROPOSITION 3.8. Let  $\mathcal{R} \geq 0$  and  $\underline{c} > 0$  be given and suppose c and  $p^0$  satisfy (2.10). Then, for any positive integers j and k such that  $k - j \geq \kappa_6 + \xi_{\mathcal{R}}^{(0)} c + \xi_{\mathcal{R}}^{(1)} c^2$ , 447448 we have 449 450

$$S_{j+1,k}^{(p)} \le \kappa_2,$$

where  $(\kappa_2, \kappa_6)$  and  $(\xi_{\mathcal{R}}^{(0)}, \xi_{\mathcal{R}}^{(1)})$  are as in (2.7) and (2.9), respectively. 451

*Proof.* Using (2.10), (3.11), Lemma 3.7(b), and the relation  $\sqrt{a} + \sqrt{b} \le \sqrt{2(a+b)}$ 452for  $a, b \in \mathbb{R}_+$ , we first have that 453

454 
$$S_{j+1,k}^{(v)} \le 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k - j}} \left( \Delta_{\phi}^{1/2} + \frac{\|p^j\| + \|p^{j-1}\| + \|p^k\|}{\chi\sqrt{c}} \right)$$
  
455 
$$\le \sqrt{\frac{4(\kappa_0^2 + \kappa_5 c)}{k - j}} \left( \Delta_{\phi}^{1/2} + \frac{3[\|p^0\| + \kappa_1 c]}{\chi\sqrt{c}} \right)$$

## This manuscript is for review purposes only.

14

456 
$$\leq \sqrt{\frac{4(\kappa_0^2 + \kappa_5 c)}{k - j}} \left( \Delta_{\phi}^{1/2} + \frac{3[\mathcal{R} + \kappa_1]\sqrt{c}}{\chi} \right)$$

$$\sqrt{\frac{8(\kappa^2 + \kappa_5 c)}{k - j}} \left( -\frac{9[\mathcal{R} + \kappa_1]^2 c}{\chi} \right)$$

$$457 \qquad \qquad \leq \sqrt{\frac{8(\kappa_0^2 + \kappa_5 c)}{k - j}} \left(\Delta_\phi + \frac{9[\mathcal{R} + \kappa_1]^2 c}{\chi^2}\right) \leq \kappa_4 \sqrt{\frac{\xi_{\mathcal{R}}^{(0)} c + \xi_{\mathcal{R}}^{(1)} c^2}{k - j}}$$

Using the above bound, Lemma 3.7(b)–(c), our assumed bound on k - j, and the 459definition of  $\kappa_2$ , we conclude that 460

461 
$$S_{j+1,k}^{(p)} \le \frac{2\chi D_{\dagger}(K_h + G_f)}{\theta d_{\dagger} \sigma_A^+} + \frac{(1-\theta) \|p^j\|}{\theta (k-j)} + \frac{S_{j+1,k}^{(v)}}{\kappa_4}$$

462 
$$\leq \frac{2\chi D_{\dagger}(K_h + G_f)}{\theta d_{\dagger}\sigma_A^+} + \frac{(1 - \theta)(\|p^0\| + \kappa_1 c)}{\theta (k - j)} + \sqrt{\frac{\kappa_6 + \xi_{\mathcal{R}}^{(0)}c + \xi_{\mathcal{R}}^{(1)}c^2}{k - j}}$$

463 
$$\leq \frac{2\chi D_{\dagger}(K_h + G_f)}{\theta d_{\dagger}\sigma_A^+} + \frac{(1-\theta)(\mathcal{R}+\kappa_1)c}{\theta(k-j)} + \sqrt{\frac{\kappa_6 + \xi_{\mathcal{R}}^{(0)}c + \xi_{\mathcal{R}}^{(1)}c^2}{k-j}}$$

464 
$$\leq \frac{2\chi D_{\dagger}(K_h + G_f)}{\theta d_{\dagger}\sigma_A^+} + \frac{\xi_{\mathcal{R}}^{(0)}c}{\theta(k-j)}$$

466

486

$$\begin{array}{l}
465\\
466
\end{array} \leq \frac{1}{\theta} \left[ 1 + \frac{2\chi D_{\dagger}(K_h + G_f)}{\theta d_{\dagger} \sigma_A^+} \right] + 1 = \kappa_2.
\end{array}$$

 $+\sqrt{\frac{\kappa_{6}+\xi_{\mathcal{R}}^{(0)}c+\xi_{\mathcal{R}}^{(1)}c^{2}}{k-i}}$ 

We end this subsection by discussing some implications of the above results. 467 Suppose  $\zeta$  is an integer satisfying  $\zeta \geq \kappa_6 + \xi_R^{(0)}c + \xi_R^{(1)}c^2 = \Theta(c^2)$ . It then follows from Proposition 3.8 that  $S_{2,\zeta}^{(p)} = \mathcal{O}(1)$  and  $S_{2\zeta,3\zeta}^{(p)} = \mathcal{O}(1)$ . Since the minimum of a set of scalars minorizes its average, there exist indices  $j_0 \in \{2, \ldots, \zeta\}$  and  $k_0 \in \{2\zeta, \ldots, 3\zeta\}$ 468 469470such that  $\|p^{j_0}\| = \mathcal{O}(1)$  and  $\|p^{k_0}\| = \mathcal{O}(1)$ . Using the fact that  $k_0 - j_0 \ge \zeta$ , the 471above bounds, and (3.10)–(3.11) with  $(j,k) = (j_0, k_0)$ , it is reasonable to expect that 472 $S_{j_0+1,k_0}^{(f)} = \mathcal{O}(1/c)$  and  $S_{j_0+1,k_0}^{(v)} = \mathcal{O}(\sqrt{c/\zeta})$ . In the next section, we give the exact steps of this argument and use the resulting bounds to prove Proposition 2.1. 473474

**3.3.** Proof of Proposition 2.1. Before presenting the proof of Proposition 2.1, 475we first give two technical results. The first one refines the bounds in Proposition 3.5 476using Proposition 3.8, while the second one gives an important implication of (2.12). 477

LEMMA 3.9. Let  $\mathcal{R} \geq 0$  and  $\underline{c} > 0$  be given and suppose  $(c, p^0)$  satisfies (2.10) for 478 some  $\mathcal{R} \geq \prime$  and  $\underline{c} > 0$ . For any integer  $\zeta$  such that  $\zeta \geq \kappa_6 + \xi_{\mathcal{R}}^{(0)}c + \xi_{\mathcal{R}}^{(1)}c^2$ , there exist  $j \in \{3, \ldots, \zeta\}$  and  $k \in \{2\zeta + 1, \ldots, 3\zeta\}$  satisfying 479480

481 (3.13) 
$$S_{j+1,k}^{(v)} \le \tilde{\kappa}_{\underline{c}}^{(0)} \sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}}, \quad S_{j+1,k}^{(f)} \le \frac{6\kappa_2}{\chi c},$$

where  $(\kappa_0, \kappa_2, \kappa_5)$  and  $\tilde{\kappa}_0$  is are as in (2.7) and (2.8), respectively. 483

*Proof.* Suppose  $\zeta \in \mathbb{N}$  satisfies  $\zeta \geq \kappa_6 + \xi_{\mathcal{R}}^{(0)}c + \xi_{\mathcal{R}}^{(1)}c^2$ . Using Proposition 3.8 with  $(j,k) = (1,\zeta)$  it holds that there exists  $3 \leq j \leq \zeta$  such that 484 485

$$\|p^{j-1}\| + \|p^{j}\| \le \frac{\sum_{i=3}^{\zeta} (\|p^{i-1}\| + \|p^{i}\|)}{\zeta - 2} \le \frac{2\sum_{i=2}^{\zeta} \|p^{i}\|}{\zeta - 2}$$

## This manuscript is for review purposes only.

$$\begin{array}{l} {}_{487} (3.14) \\ {}_{488} \end{array} = \frac{2(\zeta - 1)S_{2,\zeta}^{(p)}}{\zeta - 2} \le 4S_{2,\zeta}^{(p)} \le 4\kappa_2. \end{array}$$

489 On the other hand, using Proposition 3.8 with  $(j,k) = (2\zeta, 3\zeta)$  it holds that there 490 exists  $k \in \{2\zeta + 1, \dots, 3\zeta\}$  such that

491 (3.15) 
$$||p^k|| \le \frac{\sum_{i=2\zeta+1}^{3\zeta} ||p^i||}{\zeta} = S_{2\zeta+1,3\zeta} \le \kappa_2.$$

492 Combining (3.14), (3.15), and Proposition 3.5, it follows that

493 
$$S_{j+1,k}^{(v)} \le 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}} \left(\Delta_{\phi}^{1/2} + \frac{\|p^{j_0}\| + \|p^{j_0-1}\| + \|p^{k_0}\|}{\chi\sqrt{c}}\right)$$

494 
$$\stackrel{(3.14)-(3.15)}{\leq} 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}} \left(\Delta_{\phi}^{1/2} + \frac{5\kappa_2}{\chi\sqrt{c}}\right)$$

495  
496
$$\leq 2\sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}} \left(\Delta_{\phi}^{1/2} + \frac{5\kappa_2}{\chi\sqrt{\underline{c}}}\right) = \tilde{\kappa}_{\underline{c}}^{(0)} \sqrt{\frac{\kappa_0^2 + \kappa_5 c}{k-j}},$$

which is the first bound in (3.13). To show the other bound in (3.13), we use (3.14)and Proposition 3.8 to conclude that

$$S_{j+1,k}^{(f)} \le \frac{\|p^j\| + 2S_{j+1,k}^{(p)}}{\chi c} \le \frac{6\kappa_2}{\chi c}.$$

We now state a technical result which will be used in the proof of Proposition 2.1(c).

502 LEMMA 3.10. For any  $\mathcal{R} \ge 0$  and  $c \ge c > 0$ , the following statements hold: 503 (a) the quantity  $\mathcal{T}_c(\cdot, \cdot | \cdot, \cdot)$  defined in (2.11) satisfies

504 
$$\mathcal{T}_{c}(\rho,\eta \mid \underline{c},\mathcal{R}) \leq \left[ \left(\frac{c}{\underline{c}}\right)^{2} + \frac{c}{\underline{c} \cdot \min\{\rho^{2},\eta^{2}\}} \right] \mathcal{T}_{\underline{c}}(1,1 \mid \underline{c},\mathcal{R});$$

505 (b) if c satisfies (2.12), then  $\mathcal{T}_c(\rho, \eta | \underline{c}, \mathcal{R}) \leq c^3$ .

499

506 *Proof.* (a) This statement follows immediately from the definition of  $\mathcal{T}_c(\cdot, \cdot | \cdot, \cdot)$ 507 and the fact that for any  $c \geq \bar{c}$  any nonnegative scalars  $\alpha$ ,  $\beta$ , and  $\gamma$ , we have

508 
$$\alpha + \beta c \le (\alpha + \beta \underline{c}) \left(\frac{c}{\underline{c}}\right), \quad \alpha + \beta c + \gamma c^2 \le (\alpha + \beta \underline{c} + \gamma \underline{c}^2) \left(\frac{c}{\underline{c}}\right)^2.$$

(b) Define  $\hat{c} := \hat{c}(\rho, \eta | \underline{c}, \mathcal{R}), \varepsilon := \min\{\rho, \eta\}$ , and  $T := \mathcal{T}_{\underline{c}}(1, 1 | \underline{c}, \mathcal{R})$ , and assume that c satisfies (2.12), or equivalently,  $c \ge \hat{c}$ . To show the conclusion of (b), it suffices to show that

512 (3.16) 
$$\left[ \left(\frac{c}{\underline{c}}\right)^2 + \frac{c}{\underline{c} \cdot \varepsilon^2} \right] T \le c^3.$$

513 in view of part (a). It is easy to see that the above inequality is satisfied by any c514 such that

515 
$$c \ge \pi_{\varepsilon} := \frac{T/\underline{c}^2 + \sqrt{T^2/\underline{c}^4 + 4T/(\varepsilon^2\underline{c})}}{2}.$$

516 Since the definition of  $\hat{c}$  in (2.12) and the relation  $\sqrt{a+b} \leq \sqrt{a} + \sqrt{b}$  for  $a, b \in \mathbb{R}_+$ 517 imply that  $\hat{c} \geq \pi_{\varepsilon}$ , the conclusion of (b) follows from the assumption that  $c \geq \hat{c}$  and 518 the previous observation.

519 We now remark on Lemma 3.9. For any integer  $\zeta \geq \kappa_6 + \xi_R^{(0)}c + \xi_R^{(1)}c^2$ , it follows 520 that there exist  $i_1, i_2 \leq 3\zeta$  such that  $||v_{i_1}|| = \mathcal{O}(\sqrt{c/\zeta})$  and  $||f_{i_2}|| = \mathcal{O}(1/c)$ . Hence, 521 for some  $c = \Theta(\eta^{-1})$  and some  $\zeta \geq \Omega(\rho^{-2}\eta^{-1})$ , we can guarantee that  $||v_{i_1}|| \leq \rho$ 522 and  $||f_{i_2}|| \leq \eta$ . Clearly, if  $i_1 = i_2$  then this argument shows that a solution of 523 Problem  $S_{\rho,\eta}$  can be found in  $\mathcal{O}(\rho^{-2}\eta^{-1})$  iterations of Algorithm 2.1. In the proof (of 524 Proposition 2.1) below, we give a more involved argument that guarantees that the 525 above  $i_1$  and  $i_2$  can be chosen so that  $i_1 = i_2$ .

526 Proof of Proposition 2.1. (a) Let  $(\rho, \eta) \in \mathbb{R}^2_{++}$ ,  $p^0 \in A(\mathbb{R}^n)$ , and c > 0 be given, 527 and define

528 
$$T := \mathcal{T}_c(\rho, \eta \mid \underline{c}, \mathcal{R}), \quad r_j := \frac{\mathcal{S}_j^{(v)}}{\rho} + \frac{\mathcal{S}_j^{(f)}}{\eta} \sqrt{\frac{c^3}{j}} \quad \forall j \ge 1,$$

where  $S_j^{(v)}$  and  $S_j^{(f)}$  are as in Step 2b of Algorithm 2.1 and  $\mathcal{T}_c(\cdot, \cdot | \cdot, \cdot)$  is as in (2.11). For the sake of contradiction, suppose that Algorithm 2.1 has not terminated by the end of iteration k = T. Since Algorithm 2.1 (see its Step 2b) terminates unsuccessfully at iteration k exactly when  $r_k \leq 1$ , we will obtain the desired contradiction by showing that there exists  $k \leq T$  such that  $r_k \leq 1$ .

First, consider an arbitrary pair of integers j and k such that  $1 \le j \le k \le T$ and assume without loss of generality that k is even. Then, combining (3.18), the relations  $S_{k/2,k}^{(v)} = \mathcal{S}_k^{(v)}$  and  $S_{k/2,k}^{(f)} = \mathcal{S}_k^{(f)}$ , we easily see that

537 
$$r_k = \frac{S_{k/2,k}^{(v)}}{\rho} + \frac{c^{3/2}S_{k/2,k}^{(f)}}{\eta\sqrt{k}} = \frac{k-j+1}{k-k/2+1} \left[\frac{S_{j,k}^{(v)}}{\rho} + \frac{c^{3/2}S_{j,k}^{(f)}}{\eta\sqrt{k}}\right]$$

538 (3.17) 
$$\leq \frac{k+2}{k/2+1} \left[ \frac{S_{j,k}^{(v)}}{\rho} + \frac{c^{3/2} S_{j,k}^{(f)}}{\eta \sqrt{k}} \right] = 2 \left[ \frac{S_{j,k}^{(v)}}{\rho} + \frac{c^{3/2} S_{j,k}^{(f)}}{\eta \sqrt{k}} \right]$$

540 We now show that there exists suitable j and k so that the last expression is bounded 541 by 1 and hence that our desired contradiction follows. Note first that the definition 542 of  $T = \mathcal{T}_c(\rho, \eta)$  in (2.11) implies that  $\zeta := T/3$  satisfies the assumption of Lemma 3.9. 543 Hence, the conclusion of this lemma implies the existence of  $j \in \{3, \ldots, T/3\}$  and 544  $k \in \{2T/3 + 1, \ldots, T\}$  such that

545 
$$\frac{S_{j,k}^{(v)}}{\rho} + \frac{c^{3/2}S_{j,k}^{(f)}}{\eta\sqrt{k}} \le \frac{\tilde{\kappa}_{\underline{c}}^{(0)}\sqrt{\kappa_{0}^{2} + \kappa_{5}c}}{\rho\sqrt{k-j}} + \frac{6\kappa_{2}\sqrt{c}}{\chi\eta\sqrt{k}} \le \frac{\tilde{\kappa}_{\underline{c}}^{(0)}\sqrt{\kappa_{0}^{2} + \kappa_{5}c}}{\rho\sqrt{T/3}} + \frac{6\kappa_{2}\sqrt{c}}{\chi\eta\sqrt{T/3}}$$

546 (3.18) 
$$= \sqrt{\frac{\tilde{\kappa}_1 + \tilde{\kappa}_2 c}{\rho^2 T}} + \sqrt{\frac{\kappa_3 c}{\eta^2 T}} \le \frac{1}{4} + \frac{1}{4} = \frac{1}{2},$$

where the last inequality follows from the definition of T. Combining (3.17) and (3.18) we conclude that  $r_k \leq 1$ , which yields our desired contradiction.

(b) This follows immediately from the stopping condition in Step 2a of Algorithm 2.1 and Lemma 3.1(b).

(c) Let  $(T, r_k)$  be as in part (a) and assume that c satisfies (2.12). Assume, for contradiction, that Algorithm 2.1 does not terminate successfully. Then, by part (a), the algorithm terminates in an iteration  $k \leq T$  such that  $r_k \leq 1$ . Using the fact that  $r_k$  itself is an average of scalars, there exists  $k/2 \leq i \leq k$  such that

556 
$$\frac{\|v^i\|}{\rho} + \frac{c^{3/2}\|f^i\|}{\eta\sqrt{k}} \le \frac{S_{k/2,k}^{(v)}}{\rho} + \frac{c^{3/2}S_{k/2,k}^{(f)}}{\eta\sqrt{k}} \le 1$$

Hence, it holds that  $||v^i|| \leq \rho$  and  $||f^i|| \leq \eta \sqrt{k}c^{-3/2} \leq \eta \sqrt{T}c^{-3/2}$  where the last inequality is due to the fact that  $k \leq T$ . Moreover, the assumption that c satisfies (2.12) together with Lemma 3.10(b) then imply that  $T \leq c^3$  and, hence, that  $||f^i|| \leq$  $\eta$ . Consequently, this means that the algorithm actually terminates successfully at iteration  $i \leq k$ . We have thus established the desired contradiction and, hence, that part (c) holds.

**4. Analysis of Algorithm 2.2.** This section presents the main properties of Algorithm 2.2, including the proof of Theorem 2.2.

565 We first start with two crucial technical results.

566 PROPOSITION 4.1. The following statements hold about the  $\ell^{\text{th}}$  iteration of Algo-567 rithm 2.2:

568 (a)  $\|\bar{p}^{\ell-1}\|/c_{\ell} \leq 2\kappa_1$ , where  $\kappa_1$  is as in (2.7);

569 (b) its call to Algorithm 2.1 terminates in  $\mathcal{T}_{c_{\ell}}(\rho, \eta | c_1, 2\kappa_1)$  iterations and, if the 570  $\ell^{\text{th}}$  penalty parameter  $c_{\ell} > 0$  satisfies

571 (4.1) 
$$c_{\ell} \ge \hat{c}(\rho, \eta \,|\, c_1, 2\kappa_1),$$

then this call terminates successfully, where  $\kappa_1$ ,  $\mathcal{T}_c(\cdot, \cdot | \cdot, \cdot)$ , and  $\hat{c}(\cdot, \cdot | \cdot, \cdot)$  are as in (2.7), (2.11), and (2.12), respectively.

574 *Proof.* (a) We proceed by induction. Since  $\bar{p}^0 = 0$ , the case of  $\ell = 1$  is immediate. 575 Suppose the statement holds for some iteration  $\ell$  and, hence, that  $\|\bar{p}^{\ell-1}\| \leq 2\kappa_1 c_\ell$ . 576 Then, it follows from Lemma 3.7(b) with  $(p^0, c) = (\bar{p}^{\ell-1}, c_\ell)$  and the relation  $c_{\ell+1} =$ 577  $2c_\ell$  that

578 
$$\|\bar{p}^{\ell}\| \le \|\bar{p}^{\ell-1}\| + \kappa_1 c_\ell \le 2\kappa_1 c_\ell + \kappa_1 c_\ell = 3\kappa_1 c_\ell = \frac{3\kappa_1}{2}c_{\ell+1} < 2\kappa_1 c_{\ell+1}.$$

(b) This follows from part (a), the fact that  $\{c_\ell\}_{\ell \geq 1}$  is an increasing sequence, and Proposition 2.1 with  $(c, \underline{c}, \mathcal{R}) = (c_\ell, c_1, 2\kappa_1)$ .

581 We are now ready to give the proof of Theorem 2.2.

582 Proof of Theorem 2.2. Define the scalars

$$\hat{c} := \hat{c}(\rho, \eta \,|\, c_1, 2\kappa_1), \quad \hat{\ell} := \lceil \log_2^+(\hat{c}/c_1) \rceil, \quad \mathcal{T}_{c_\ell} := \mathcal{T}_{c_\ell}(\rho, \eta \,|\, c_1, 2\kappa_1),$$

where  $\hat{c}(\cdot, \cdot | \cdot, \cdot)$  is as in (2.12). Proposition 4.1(b) and the update rule for  $c_{\ell}$  imply that Algorithm 2.2 performs at most  $\hat{\ell}$  iterations, and terminates with a pair that solves Problem  $S_{\rho,\eta}$ . Moreover, the total number of iterations of Algorithm 2.1 (performed by all of Algorithm 2.2's calls to it) is bounded by  $\sum_{\ell=1}^{\hat{\ell}} \mathcal{T}_{c_{\ell}}$ . Now, using Lemma 3.10(a) with  $\underline{c} = c_1$ , it follows that

590 (4.2) 
$$\frac{\sum_{\ell=1}^{\hat{\ell}} \mathcal{T}_{c_{\ell}}}{T_{1}} \leq \frac{\sum_{\ell=1}^{\hat{\ell}} c_{\ell}^{2}}{c_{1}^{2}} + \frac{\sum_{\ell=1}^{\hat{\ell}} c_{\ell}}{c_{1} \varepsilon^{2}} = \sum_{\ell=1}^{\hat{\ell}} 2^{2(\ell-1)} + \frac{\sum_{\ell=1}^{\hat{\ell}} 2^{(\ell-1)}}{\varepsilon^{2}} \leq 4^{\hat{\ell}} + \frac{2^{\hat{\ell}}}{\varepsilon^{2}},$$
18

where  $(T_1, \varepsilon)$  are as in (2.13). We now derive suitable bounds for  $4^{\hat{\ell}}$  and  $2^{\hat{\ell}}$ . Using the definitions of  $\hat{c}$  and  $\hat{\ell}$ , and the definition of  $(E_0, E_1)$  in (2.15), we first have that

593 
$$2^{\hat{\ell}} \le \max\left\{2, 2^{(1+\log_2 \hat{c}/c_1)}\right\} \le 2\max\left\{1, \frac{\hat{c}}{c_1}\right\} = 2\max\left\{1, \frac{1}{c_1^3}\left(T_1 + \frac{\sqrt{c_1^3}T_1}{\varepsilon}\right)\right\}$$

594 595

596 Combining the above inequality above with the bound  $(a+b)^2 \leq 2a^2+2b^2$  for  $a, b \in \mathbb{R}$ , 597 it is also easy to see that

598 (4.4) 
$$4^{\hat{\ell}} \le (2^{\hat{\ell}})^2 \le 2E_0^2 + \frac{2E_1^2}{\varepsilon^2}.$$

(4.3)  $\leq 2\left(1+\frac{T_1}{c_1^3}+\frac{1}{\varepsilon}\sqrt{\frac{T_1}{c_1^3}}\right)=E_0+\frac{E_1}{\varepsilon}.$ 

600 The conclusion now follows by applying (4.4) and (4.3) to (4.2).

**5.** Numerical Experiments. This section examines the performance of the proposed DP.ADMM (Algorithm 2.2) for finding stationary points of a nonconvex three-block distributed quadratic programming problem. Specifically, given a radius  $\gamma > 0$  and a dimension  $n \in \mathbb{N}$ , it considers the three-block problem

605 
$$\min_{(x_1, x_2, x_3) \in \mathbb{R}^n \times \mathbb{R}^n} - \sum_{i=1}^2 \left[ \frac{\alpha_i}{2} \|x_i\|^2 + \langle x_i, \beta_i \rangle \right]$$

606 s.t. 
$$\|x\|_{\infty} \leq \gamma$$

607 
$$x_1 - x_3 = 0,$$

$$x_2 - x_3 = 0$$

610 where  $\{\alpha_i\}_{i=1}^2 \subseteq [0,1], \{\beta_i\}_{i=1}^2 \subseteq [0,1]^n$ , and the entries of these quantities are 611 sampled from the uniform distribution on [0,1]. It is clear that the above problem is 612 an instance of (1.1) if we take  $h_i$  to be the indicator of the set  $\{x \in \mathbb{R}^n : ||x||_{\infty} \leq \gamma\}$ 613 for  $i = 1, \ldots, 3$ . At the end of this section, we give some elucidating remarks.

Before presenting the results, we first describe the algorithms tested. The first 614 set of algorithms, labeled DP1–DP2, are modifications of Algorithm 2.2. Specifically, 615both DP1 and DP2 replace the original definition of  $S_k^{(f)}$  (resp.  $S_k^{(f)}$ ) in Step 2b of Algorithm 2.1 with  $2\sum_{i=1}^k ||v^i||/[k+2]$  (resp.  $2\sum_{i=1}^k ||Ax^i - d||/[k+2]$ ) and choose  $(\lambda, c_1) = (1/2, 1)$ . Moreover, DP1 chooses  $(\theta, \chi) = (0, 1)$  while DP2 chooses  $(\theta, \chi) = (1/2, 1/(2))$  which extinct (2, 0) the extinct (2, 0) to (2, 0). 616 617 618  $(\theta, \chi) = (1/2, 1/18)$  which satisfies (2.6) at equality. The second set of algorithms, 619 620 labeled SDD1–SDD3, are instances of the SDD-ADMM of [28] for different values of the penalty parameter  $\rho$ . Specifically, all of these instances uses the parameters 621  $(\omega, \theta, \tau) = (4, 2, 1)$ , following the same choice as in [28, Section 5.1], and select the fol-622 lowing curvature constants:  $(M_h, K_h, J_h, L_h) = (4\gamma, 1, 1, 0)$ . Moreover, SDD1–SDD3 623 respectively choose the penalty parameter  $\rho$  to be 0.1, 1.0, and 10.0, and termination 624 of the method occurs when the norm of the stationary residual  $\xi^k$  and feasibility are 625 both less than a given numerical tolerance.

627 The results of our experiment are now given in Tables 5.1–5.2, which present 628 both iteration counts and runtimes for either varying choices of  $\gamma$  (Table 5.1) or *n* 629 (Table 5.2). We now describe a few more details about these experiments and tables. 630 First, the starting point for all methods is the zero vector and the numerical tolerances 631 (e.g.,  $\rho$  and  $\eta$  in DP1–DP2) for each method were set to be 10<sup>-9</sup>. Second, the bolded

text in the tables highlight the method that performed the best in terms of iteration count. Third, we imposed an iteration limit of 100,000 and marked the runs which did not terminate by this limit with a '-' symbol. Fourth, the experiments were implemented and executed in Matlab R2021b on a Windows 64-bit desktop machine with 12GB of RAM and two Intel(R) Xeon(R) Gold 6240 processors, and the code is readily available online<sup>3</sup>.

TABLE 5.2										
		Resi	ults with	$\gamma = 10$	00 and	differe	ent val	lues of	n	

From the results in Tables 5.1–5.2, we see that DP1 performed the best in terms of iteration count and DP2 had iteration counts that were close to DP1. On the other hand, SDD2 outperformed its other SDD-ADMM variant on all problems except one. Finally, notice that the DP.ADMM variants scaled better against the dimension ncompared to the SDD-ADMM variants.

To close this section, we give some elucidating remarks. First, we excluded the algorithm in [15] due to its poor iteration complexity bound and the fact that it is an algorithm applied to a reformulation of (1.1) rather than to (1.1) directly. Second, we had to choose different values of the penalty parameter  $\rho$  for the SDD-ADMM variants because the analysis in [28] did not present a practical way of adaptively updating  $\rho$  (note that the "adaptive" method in [28, Algorithm 3.2] is not practical because it requires an estimate of  $\sup_{x \in \mathcal{H}} \phi(x) - \inf_{x \in \mathcal{H}} \phi$  for (1.1)).

650 **6.** Concluding Remarks. The analysis of this paper also applies to instances 651 of (1.1) where f is not necessarily differentiable on  $\mathcal{H}$  as in our condition (A5), but 652 instead satisfies a more relaxed version of (A5), namely: for every  $x \in \mathcal{H}$ , the function 653  $f(x_{\leq t}, \cdot, x_{>t})$  has a Fréchet subgradient at  $x_t$ , denoted by  $\nabla_{x_t} f(x_{\leq t}, x_{>t})$ , and (2.3) 654 is satisfied for every  $t = 1, \ldots, B - 1$ . Hence, our analysis immediately applies to

<sup>&</sup>lt;sup>3</sup>See https://github.com/wwkong/nc\_opt/tree/master/tests/papers/dp\_admm.

the case where f(z) is of the form  $\sum_{t=1}^{B} f_t(z_t)$  in which, for every  $t = 1, \ldots, B$ , the function  $f_t(\cdot) + m_t \| \cdot \|^2 / 2 + \delta_{\mathcal{H}_t}(\cdot)$  is convex and has a subgradient everywhere in  $\mathcal{H}_t$ . 655 656 We now discuss some possible extensions of our analysis in this paper. First, 657

our analysis was done under the assumption that  $\mathcal{H}$  is bounded (see (A3)), but 658 it is straightforward to see that it is still valid under the weaker assumption that 659  $\sup_{k\geq 1} \|x^k - z_{\dagger}\| \leq D_{\dagger}$  for some  $D_{\dagger} > 0$  where  $z_{\dagger}$  is as in (A6). It would be interest-660 ing to extend the analysis in this paper to the case where  $\mathcal{H}$  is unbounded, possibly 661 by assuming conditions on the sublevel sets of  $\phi$  which guarantee that the aforemen-662 tioned bound holds. Second, the convergence of Algorithm 2.2 is established under 663 the assumption that exact solutions to the subproblems in Step 1 of Algorithm 2.1 664 are easy to obtain. We believe that convergence can also be established when only 665 666 inexact solutions, e.g.,

667 (6.1) 
$$x_t^k \approx \operatorname*{argmin}_{u_t \in \mathbb{R}^{n_t}} \left\{ \lambda \mathcal{L}_c^{\theta}(x_{< t}^k, u_t, x_{> t}^{k-1}; p^{k-1}) + \frac{1}{2} \|u_t - x_t^{k-1}\|^2 \right\}$$

are available. For example, one could consider applying an accelerated composite 668 gradient (ACG) method to the problem associated with (6.1) so that  $x_t^k$  satisfies 669

670 
$$\exists r_t^k \quad \text{s.t.} \quad \begin{cases} r_k^t \in \partial \left( \lambda \mathcal{L}_c^{\theta}(x_{< t}^k, \cdot, x_{> t}^{k-1}; p^{k-1}) + \frac{1}{2} \| \cdot - x_t^{k-1} \|^2 \right) (x_t^k), \\ \| r_t^k \|^2 \le \sigma^2 \| x_t^{k-1} - x^k \|^2, \end{cases}$$

for some  $\sigma \in (0, 1)$ . 671

#### Appendix A. Proof of Lemma 3.2 and Lemma 3.4(a)–(b). 672

Before giving the proofs, we present some auxiliary results. To avoid repetition, 673 assume the reader is already familiar with (3.1)–(3.3). 674 we

The proof of the first result can be found in [19, Lemma B.2]. 675

LEMMA A.1. For any  $(\zeta, \theta) \in [0, 1]^2$  satisfying  $\zeta \leq \theta^2$  and  $(a, b) \in \mathbb{R}^n \times \mathbb{R}^n$ , we 676 have that 677

678 (A.1) 
$$||a - (1 - \theta)b||^2 - \zeta ||a||^2 \ge \left[\frac{(1 - \zeta) - (1 - \theta)^2}{2}\right] \left(||a||^2 - ||b||^2\right).$$

The next result establishes some general bounds given by the updates in (1.5). 679

LEMMA A.2. For every  $i \geq 1$ , index  $t = 1, \ldots, B$ , and  $u_t \in \mathcal{H}_t$ , it holds that 680

*Proof.* Let  $i \geq 1, t = 1, \ldots, B$ , and  $u_t \in \mathcal{H}_t$  be fixed, and define  $\mu := 1 - \lambda m_t$ 684 and  $\|\cdot\|_{\alpha}^2 := \langle \cdot, (\mu I + \lambda c A_t^* A_t)(\cdot) \rangle$ . Since the prox stepsize  $\lambda$  is chosen in (0, 1/(2m)]and  $m \ge m_t$  in view of (2.7), it follows that  $\mu \ge 1/2$ . Using the optimality of  $x_t^i$ , assumption (A4), and the fact that  $\lambda \mathcal{L}_c^{\theta}(x_{\le t}^i, \cdot, x_{>t}^{i-1}; p^{i-1}) + \|\cdot -x_t^{i-1}\|^2/2$  is 1-strongly 686 687 convex with respect to  $\|\cdot\|_{\alpha}^2$ , it follows that 688

$$\overset{691}{}_{692} = \lambda \mathcal{L}_c^{\theta}(x_{t}^{i-1}; p^{i-1}) + \frac{1}{2} \|u_t - x_t^{i-1}\|^2 - \frac{\mu}{2} \|u_t - x_t^i\|^2 - \frac{\lambda c}{2} \|A_t(u_t - x_t^i)\|^2.$$

## This manuscript is for review purposes only.

#### 693 We are now ready to give the proof of Lemma 3.2.

698

Proof of Lemma 3.2. (a) Using the definition of  $\mathcal{L}^{\theta}_{c}(\cdot; \cdot)$  in (1.4) and the relation 694 in Lemma 3.1(a), we conclude that 695

696 
$$\mathcal{L}_{c}^{\theta}(x^{i};p^{i}) - \mathcal{L}_{c}^{\theta}(x^{i};p^{i-1}) = (1-\theta)\left\langle\Delta p^{i},f^{i}\right\rangle = \left(\frac{1-\theta}{\chi c}\right)\left\|\Delta p^{i}\right\|^{2} + \frac{a_{\theta}}{\chi c}\left\langle\Delta p^{i},p^{i-1}\right\rangle$$

697 
$$= \left(\frac{1-\theta}{\chi c}\right) \|\Delta p^i\|^2 + \frac{a_\theta}{\chi c} \left(\langle p^i, p^{i-1} \rangle - \|p^i\|^2\right)$$

$$= \left(\frac{1-\theta}{\chi c}\right) \|\Delta p^{i}\|^{2} + \frac{a_{\theta}}{\chi c} \left(\langle p^{i}, p^{i-1} \rangle - \|p^{i-1}\|^{2}\right)$$
$$= \left(\frac{1-\theta}{\chi c}\right) \|\Delta p^{i}\|^{2} + \frac{a_{\theta}}{\chi c} \left(\frac{1}{2}\|p^{i}\|^{2} - \frac{1}{2}\|\Delta p^{i}\|^{2} - \frac{1}{2}\|p^{i-1}\|^{2}\right)$$

699 (A.2) 
$$= \frac{b_{\theta}}{2\chi c} \|\Delta p^i\|^2 + \frac{a_{\theta}}{2\chi c} \left(\|p^i\|^2 - \|p^{i-1}\|^2\right)$$

(b) Using the definition of m in (2.7) and summing the inequality of Lemma A.2 701 with  $u_t = x_t^{i-1}$  from t = 1 to B, we have that 702

$$\begin{array}{l} 703 \quad \left(1 - \frac{\lambda m}{2}\right) \|\Delta x^{i}\|^{2} + \frac{\lambda c}{2} \sum_{t=1}^{B} \|A_{t} \Delta x_{t}^{i}\|^{2} \leq \sum_{i=1}^{t} \left(1 - \frac{\lambda m_{t}}{2}\right) \|\Delta x_{t}^{i}\|^{2} + \frac{\lambda c}{2} \sum_{t=1}^{B} \|A_{t} \Delta x_{t}^{i}\|^{2} \\ \leq \lambda \left[\mathcal{L}_{c}^{\theta}(x^{i-1};p^{i-1}) - \mathcal{L}_{c}^{\theta}(x^{i};p^{i-1})\right]. \end{array}$$

706 The conclusion now follows from dividing the above inequality by  $\lambda$  and using the fact that  $\lambda \leq 1/m$ . 707

(c) Note that the definition of  $b_{\theta}$  in (3.1) and (2.6) imply 708

$$\zeta := 2B\chi b_{\theta} \le \theta^2.$$

Hence, using the definition of  $\gamma_{\theta}$  in (3.1), and Lemma A.1 with  $(a, b) = (\Delta p^i, \Delta p^{i-1})$ 710it follows that 711

712 (A.3) 
$$\|\Delta p^{i} - (1-\theta)\Delta p^{i-1}\|^{2} \ge 2B\chi b_{\theta}\|\Delta p^{i}\|^{2} + \chi\gamma_{\theta}\left(\|\Delta p^{i}\|^{2} - \|\Delta p^{i-1}\|^{2}\right).$$

Using (A.3) at i and i - 1, Lemma 3.1(a), and the relation  $||a||_1^2 \le n ||a||_2^2$  for  $a \in \mathbb{R}^n$ , 713 714we have that

715 
$$\frac{c}{4} \sum_{t=1}^{B} \|A_t \Delta x_t^i\|^2 \ge \frac{c}{4B} \|A \Delta x^i\|^2 = \frac{\|\Delta p^i - (1-\theta)\Delta p^{i-1}\|^2}{4B\chi^2 c}$$

716 
$$\geq \frac{1}{4B\chi c} \left[ 2Bb_{\theta} \|\Delta p^{i}\|^{2} + \gamma_{\theta} \left( \|\Delta p^{i}\|^{2} - \|\Delta p^{i-1}\|^{2} \right) \right]$$

$$= \frac{b_{\theta}}{2\chi c} \|\Delta p^{i}\|^{2} + \frac{\gamma_{\theta}}{4B\chi c} \left( \|\Delta p^{i}\|^{2} - \|\Delta p^{i-1}\|^{2} \right).$$

#### Next, we give the proof of Lemma 3.4(a)-(b). 719

Proof of Lemma 3.4(a)–(b). (a) Using Lemma 3.2(a), the definition of  $\mathcal{L}_c^{\theta}(\cdot; \cdot)$  in (1.4), the fact that  $\theta \in (0, 1)$ , and the relations  $2\langle a, b \rangle \leq ||a||^2 + ||b||^2$  and  $||a + b||^2 \leq 2||a||^2 + 2||b||^2$  for  $a, b \in \mathbb{R}^n$ , it follows that 720 721 722

723 
$$\mathcal{L}_{c}^{\theta}(x^{j};p^{j}) = \phi(x^{j}) + (1-\theta) \langle p^{i}, f^{i} \rangle + \frac{c}{2} \|f^{i}\|^{2}$$
724 
$$\stackrel{\text{L.3.2(a)}}{=} \frac{(1-\theta)}{\chi c} \langle p^{i}, p^{i} - (1-\theta)p^{i-1} \rangle + \frac{1}{2c\chi^{2}} \|p^{i} - (1-\theta)p^{i-1}\|^{2}$$

725 
$$\leq \frac{(1-\theta)}{2\chi c} \|p^i\|^2 + \frac{(1-\theta)}{2\chi c} \|p^i - (1-\theta)p^{i-1}\|^2 + \frac{1}{2\chi^2 c} \|p^i - (1-\theta)p^{i-1}\|^2$$

26 
$$\leq \frac{1}{2\chi c} \|p^i\|^2 + \frac{1}{\chi^2 c} \|p^i - (1-\theta)p^{i-1}\|^2$$

$$\leq \frac{1}{2\chi c} \|p^i\|^2 + \frac{2}{\chi^2 c} \|p^i\|^2 + \frac{2}{\chi^2 c} \|p^{i-1}\|^2 \leq \frac{3(\|p^i\|^2 + \|p^{i-1}\|^2)}{\chi^2 c}$$

729 (b) It holds that

730 
$$\mathcal{L}_c^{\theta}(x^k; p^k) = \phi(x^k) + (1-\theta) \left\langle p^k, f^k \right\rangle + \frac{c}{2} \|f^k\|^2$$

731 
$$= \phi(x^k) + \frac{1}{2} \left\| \frac{(1-\theta)p^k}{\sqrt{c}} + \sqrt{c}f^k \right\|^2 - \frac{(1-\theta)^2 \|p^k\|^2}{2c}$$

732  
733 
$$\geq \phi(x^k) - \frac{(1-\theta)^2 \|p^k\|^2}{2c} \geq \phi(x^k) - \frac{\|p^k\|^2}{2c}.$$
